ABSTRACT

In earlier work with David Hobson (Mathematical Finance 2007) we established necessary and sufficient conditions under which a given set of traded vanilla option prices is consistent with an arbitrage-free model. Here we ask, given that these conditions are satisfied, what are the bounds on the price of a variance swap written on the same underlying asset (given that its price is a continuous function of time). It turns out that there is a non-trivial lower bound, computed by a dynamic programming algorithm, but there is no upper bound unless we impose further conditions on the price process. In view of the well-known connection between variance swaps and the log option, appropriate conditions relate to left-tail information on the price \( S(T) \) at the option exercise time \( T \), such as existence of a conditional inverse power moment. One can also reverse the question and ask what information a variance swap provides about the underlying distribution.
