STAT22000 Autumn 2013 Lecture 25

Yibi Huang

November 25-27, 2013
9.1 Inference For Two-Way Tables
9.2 Formulas and Models for Two-Way Tables

Lecture 25-1

## Marginal Distributions

$$
\begin{aligned}
\text { marginal distribution of the row variable } & =\frac{\text { row total }}{\text { overall total }} \\
\text { marginal distribution of the column variable } & =\frac{\text { column total }}{\text { overall total }}
\end{aligned}
$$

| Depression | Single | Marital Status <br> Married | Wid/Div | Row <br> Total |
| :--- | :---: | :---: | :--- | :---: |
| Severe |  |  |  | $\frac{57}{159}=0.358$ |
| Moderate |  |  |  | $\frac{76}{159}=0.478$ |
| Mild |  |  | $\frac{26}{159}=0.164$ |  |
| Column Total | $\frac{54}{159}=0.340$ | $\frac{69}{159}=0.434$ | $\frac{36}{159}=0.226$ | $\frac{159}{159}=1.000$ |

The table tells us, $34.0 \%$ of people in the sample are single, $43.4 \%$ married, and $22.6 \%$ widowed or divorced.

Also, $35.8 \%$ of people in the sample are severely depressed, 47.8\% moderately, and $16.4 \%$ mildly.

Lecture 25-3

## Conditional Distribution

Likewise, the observed conditional distribution distribution of the column variable given the row variable is the cell counts divided by the corresponding row totals.

Example. The conditional distributions of level of depression given marital status is

| Depression | Marital Status <br> Married |  |  | Wid/Div |
| :--- | :---: | :---: | :---: | :---: | | Row |
| :---: |
| Total |$|$|  | Single | $\frac{22}{57}=0.281$ | $\frac{22}{57}=0.386$ | $\frac{19}{57}=0.333$ |
| :--- | :---: | :---: | :---: | :---: |
| $\frac{57}{57}=1$ |  |  |  |  |
| Severe | $\frac{29}{76}=0.382$ | $\frac{33}{76}=0.434$ | $\frac{14}{76}=0.184$ | $\frac{76}{76}=1$ |
| Moderate | $\frac{9}{26}=0.346$ | $\frac{14}{26}=0.538$ | $\frac{3}{26}=0.115$ | $\frac{26}{26}=1$ |
| Mild | $\frac{54}{159}=0.340$ | $\frac{69}{159}=0.434$ | $\frac{36}{159}=0.226$ | $\frac{159}{159}=1$ |
| Column Total |  |  |  |  |

E.g., $34.6 \%$ of the people with mild depression in the sample are single, $53.8 \%$ are married, and $11.5 \%$ are widowed or divorced.

## Two-Way Tables

Two-way tables, also known as contingency tables, often formed from counts of two categorical variables.

Example: Study of 159 depression patients categorized by

- level of depression (severe, moderate, mild), which is the row variable in the table
- marital status (single, married, widowed/divorced), which is the column variable in the table

| Depression | Marital Status |  |  |  |
| :--- | :---: | :---: | :---: | :---: |
|  | Total |  |  |  |
|  | Single | Married | Wid/Div |  |
| Severe | 16 | 22 | 19 | 57 |
| Moderate | 29 | 33 | 14 | 76 |
| Mild | 9 | 14 | 3 | 26 |
| Total | 54 | 69 | 36 | 159 |

- Each combination of values of the two combination defines a cell.

Lecture 25-2

## Conditional Distribution

The observed conditional distribution distribution of the row variable given the column variable is the cell counts divided by the corresponding column totals.

Example. The conditional distributions of level of depression given marital status is

| Depression | Marital Status |  |  | Row <br> Total |
| :--- | :---: | :---: | :---: | :---: |
| Severe | $\frac{16}{54}=0.296$ | $\frac{22}{69}=0.319$ | $\frac{19}{36}=0.528$ | $\frac{57}{159}=0.358$ |
| Moderate | $\frac{29}{54}=0.537$ | $\frac{33}{69}=0.478$ | $\frac{14}{36}=0.389$ | $\frac{76}{159}=0.478$ |
| Mild | $\frac{9}{54}=0.167$ | $\frac{14}{69}=0.203$ | $\frac{3}{36}=0.083$ | $\frac{26}{159}=0.164$ |
| Column Total | $\frac{54}{54}=1.000$ | $\frac{69}{69}=1.000$ | $\frac{36}{36}=1.000$ | $\frac{159}{159}=1.000$ |

E.g., $29.6 \%$ of the single people in the sample are severely depressed, $53 \%$ moderately, and $16.7 \%$ mildly.

Lecture 25-4

The barplots below show the conditional distributions of level of depression given marital status.

Is this simply chance variation, or the two variables (level of depression, marital status) are indeed associated?

- If level of depression is independent of marital status, we expect the conditional distributions to be similar regardless of marital status.
- However, widowed/divorced patients seem to have a different conditional distribution from single or married patients.
- Is the difference statistically significant?

Lecture 25-7

## Expected Counts

The expected counts for the depression and marital status data are

| Depression | Marital Status |  |  | Row <br> Total |
| :---: | :---: | :---: | :---: | :---: |
|  | Single | Married | Wid/Div |  |
| Severe | $\frac{57 \times 54}{159}=19.37$ | $\frac{57 \times 69}{159}=24.74$ | $\frac{57 \times 36}{159}=12.91$ | 57 |
| Moderate | $\frac{76 \times 54}{159}=25.81$ | $\frac{76 \times 69}{159}=32.98$ | $\frac{76 \times 36}{159}=17.21$ | 76 |
| Mild | $\frac{26 \times 54}{159}=8.83$ | $\frac{26 \times 69}{159}=11.28$ | $\frac{26 \times 36}{159}=5.89$ | 26 |
| Column Total | 54 | 69 | 36 | 159 |

Note the expected cell counts need NOT be whole numbers.

Lecture 25-9

Chi-Square $\left(\chi^{2}\right)$ Distribution

- Just like $t$-distribution, there is one $\chi^{2}$ curve with each number of degree of freedom
- All $\chi^{2}$-curves are right-skewed
- The larger the degrees of freedom, the more flatten out and the far to the right the $\chi^{2}$ curves

## Expected Cell Counts

When the column variable and the row variable are independent, the conditional distribution and of the column given the row, which is

$$
\frac{\text { count in a cell }}{\text { row total }}
$$

will be the same as the marginal distribution of the column variable, which is

$$
\frac{\text { column total }}{\text { overall total }}
$$

That is,

$$
\frac{\text { count in a cell }}{\text { row total }}=\frac{\text { column total }}{\text { overall total }}
$$

Thus the expected cell counts under the independence assumption are

$$
\text { expected count in a cell }=\frac{\text { row total } \times \text { column total }}{\text { overall total }}
$$

Lecture 25-8

## Test for Independence

1. First we state the null and alternative hypotheses:
$H_{0}$ : the row and column variables are independent
$H_{a}$ : the row and column variables are dependent
2. Construct table of expected counts using the formula expected cell count $=\frac{\text { row total } \times \text { column total }}{\text { overall total }}$
3. Compare expected with observed counts
4. If $\mathrm{H}_{0}$ is true, the observed counts and expected counts should be "close"
5. Their differences are measured using a chi-squared statistic

$$
\chi^{2}=\sum_{\text {all cells }} \frac{(\text { Observed count }- \text { Expected count })^{2}}{\text { Expected count }}
$$

6. The larger the $\chi^{2}$-statistic, the stronger is the evidence against $\mathrm{H}_{0}$ (and the more likely to reject $\mathrm{H}_{0}$ )

Lecture 25-10

|  | The $\chi^{2}$-curve, with degrees of freedom shown along the left of the table. |  |  |  |  | $\mathbb{R}$ is shown in the body of the table |  |  |  |  |  |  |

| 5 | 6.63 | 7.29 | 8.12 | 9.24 | 11.07 | 12.83 | 13.39 | 15.09 | 16.75 | 18.39 | 20.52 | 22.11 |  |  |  |  |  |  |  |  |  |
| 6 | 7.84 | 8.56 | 9.45 | 10.64 | 12.59 | 14.45 | 15.03 | 16.81 | 18.55 | 20.25 | 22.46 | 24.10 |  |  |  |  |  |  |  |  |  |
| 7 | 9.04 | 9.80 | 10.75 | 12.02 | 14.07 | 16.01 | 16.62 | 18.48 | 20.28 | 22.04 | 24.32 | 26.02 |  |  |  |  |  |  |  |  |  |
| 8 | 10.22 | 11.03 | 12.03 | 13.36 | 15.51 | 17.53 | 18.17 | 20.09 | 21.95 | 23.77 | 26.12 | 27.87 |  |  |  |  |  |  |  |  |  |
| 9 | 11.39 | 12.24 | 13.29 | 14.68 | 16.92 | 19.02 | 19.68 | 21.67 | 23.59 | 25.46 | 27.88 | 29.67 |  |  |  |  |  |  |  |  |  |
| 10 | 12.55 | 13.44 | 14.53 | 15.99 | 18.31 | 20.48 | 21.16 | 23.21 | 25.19 | 27.11 | 29.59 | 31.42 |  |  |  |  |  |  |  |  |  |

Q: Find the area under the $\chi^{2}$-curve with 5 degrees of freedom to
the right of (a) 6.63
(b) 9.24
(c) 15.09
A:
(a) $\quad 0.25$
(b) 0.1
(c) 0.01

Q: Find the area under the $\chi^{2}$-curve with 10 degrees of freedom to the right of 18 .
A: $\qquad$ between 0.1 and 0.05 .

Lecture 25-13

Why $(r-1)(c-1)$ degrees of freedom?

Imagine a table with $r$ rows and $c$ columns, and fixed row and column totals. (This table has rc cells.)
After we fill in $c-1$ values for a row, we can deduce the $c$-th value.
Likewise, we only need $r-1$ values to specify a column.
In total, there are $(r-1)(c-1)$ freely varying values.

| $*$ | $*$ | $*$ |  | $N_{1+}$ |
| :---: | :---: | :---: | :---: | :---: |
| $*$ | $*$ | $*$ |  | $N_{2+}$ |
|  |  |  |  | $N_{3+}$ |
| $N_{+1}$ | $N_{+2}$ | $N_{+3}$ | $N_{+4}$ | $N_{++}$ |

Lecture 25-15

## Back to the Depression Example

The table is $3 \times 3$, so there are $(r-1)(c-1)=2 \times 2=4$ degrees of freedom.

|  | Upper-tail probability $p$ |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| df | 0.25 | 0.20 | 0.15 | 0.10 | 0.05 | 0.025 | 0.02 | 0.01 | 0.005 | 0.0025 | 0.001 | .0005 |  |  |  |
| $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ |  |  |  |
| 4 | 5.39 | 5.99 | 6.74 | 7.78 | 9.49 | 11.14 | 11.67 | 13.28 | 14.86 | 16.42 | 18.47 | 20.00 |  |  |  |
| $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ |  |  |  |

From the $\chi^{2}$-table above, we see that 6.83 is between 6.74 and 7.78. Thus the $P$-value is between 0.15 and 0.10 , not rejecting $\mathrm{H}_{0}$ at level 0.05 .

The evidence is not strong enough to say the level of depression is associated with marital status.

## Distribution of the Chi-square Statistic

The $\chi^{2}$ statistic defined on page 11 is approximately $\chi^{2}$ distributed with $(r-1)(c-1)$ degrees of freedom, where $r=\#$ of rows, and $c=\#$ of columns in the table.

- e.g., the depression and marital status table has 3 rows and 3 columns, so $d f=(3-1)(3-1)=4$.
The $P$-value approximately is the area of the upper-tail under the $\chi^{2}$-curve with $(r-1)(c-1)$ degrees of freedom beyond the chi-square statistic.

Lecture 25-14

## Back to the Depression Example

The table below shows the observed counts and the expected counts (in parentheses)

| Depression | Marital Status |  |  |  |
| :--- | :---: | :---: | :---: | :---: |
| Row |  |  |  |  |
|  | Single | Married | Wid/Div | Total |
| Severe | 16 | 22 | 19 | 57 |
|  | $(19.36)$ | $(24.74)$ | $(12.90)$ |  |
| Moderate | 29 | 33 | 14 | 76 |
| Mild | $(25.81)$ | $(32.98)$ | $(17.21)$ |  |
|  | 9 | 14 | 3 | 26 |
|  | $(8.83)$ | $(11.28)$ | $(5.89)$ |  |
| Column Total | 54 | 69 | 36 | 159 |

The observed value of the $\chi^{2}$ test statistic is

$$
\begin{aligned}
x^{2} & =\frac{(16-19.36)^{2}}{19.36}+\frac{(22-24.74)^{2}}{24.74}+\ldots+\frac{(3-5.89)^{2}}{5.89} \\
& =6.83
\end{aligned}
$$

Lecture 25-16

Example: Do Fighter Pilots Father More Daughters? (1)

It is conventional wisdom in military squadrons that pilots tend to father more girls than boys. Snyder (1961) gathered data for military fighter pilots. The gender of the pilot's offspring were tabulate for 3 kinds of flight duty during the month of conception.

| Father's Activity | Female <br> offspring | Male <br> offspring | Row <br> Total |
| :--- | :---: | :---: | :---: |
| Flying Fighters | 51 | 38 | 89 |
| Flying Transports | 14 | 16 | 30 |
| Not Flying | 38 | 46 | 84 |
| Column Total | 103 | 100 | 203 |

Example: Do Fighter Pilots Father More Daughters? (2)
Now we have 3 populations of pilot fathers, those flying fighters, those flying transporters, and those not flying.

Let $p_{f}, p_{t}$, and $p_{n}$ be respectively the proportion who father girls rather than boys in the 3 populations.

If the gender of their children is independent of their duty during the month of conception, then we expect

$$
p_{f}=p_{t}=p_{n}
$$

So for this example, the hypotheses of the chi-square test of independence can be rephrased as
$\mathrm{H}_{0}: p_{f}=p_{t}=p_{n}$.
$\mathrm{H}_{a}: p_{f}, p_{t}, p_{n}$ are not all equal

Lecture 25-19

## Example: Jane Austen \& Her Imitator

People have applied statistical techniques to distinguish the literary style of authors and imitators. The following is an example. When Jane Austen died, she left the novel Sanditon partially completed, and an admirer finished it. Morton (1978) compared the style of the imitator's work, and two other novels by Austen.

| Word | Sense and <br> Sensibility | Emma | Sanditon I <br> (by Austen) | Sanditon II <br> (by Imitators) |
| :---: | :---: | :---: | :---: | :---: |
| a | 147 | 186 | 101 | 83 |
| an | 25 | 26 | 11 | 29 |
| this | 32 | 39 | 15 | 15 |
| that | 94 | 105 | 37 | 22 |
| with | 59 | 74 | 28 | 43 |
| without | 18 | 10 | 10 | 4 |
| Total | 375 | 440 | 202 | 196 |

Lecture 25-21

To compare Austen and her imitator, we can pool all Austen's work together as her style did not change.

| Word | Imitator | Austen |
| :---: | :---: | :---: |
| a | 83 | 434 |
|  | $(83.5)$ | $(433.5)$ |
| an | 29 | 62 |
|  | $(14.7)$ | $(76.3)$ |
| this | 15 | 86 |
|  | $(16.3)$ | $(84.7)$ |
| that | 22 | 236 |
|  | $(41.7)$ | $(216.3)$ |
| with | 43 | 161 |
|  | $(33.0)$ | $(171.0)$ |
| without | 4 | 38 |
|  | $(6.8)$ | $(35.2)$ |

$\chi^{2}=32.81$ with df $=(6-1) \times(2-1)=5$. $P$-value is less than 0.0005 .

The imitator was not successful in imitating this aspect of Austen's style.

|  | Upper-tail probability $p$ |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| df | $\ldots$ | 0.05 | 0.025 | 0.02 | 0.01 | 0.005 | 0.0025 | 0.001 | .0005 |
| 5 | $\ldots$ | 11.07 | 12.83 | 13.39 | 15.09 | 16.75 | 18.39 | 20.52 | 22.11 |

Example: Do Fighter Pilots Father More Daughters? (3)

| Father's Duty | Gender Girl | ffspring Boy | Row |
| :---: | :---: | :---: | :---: |
| Flying obs'd | 51 | 38 | 89 |
| Fighters exp'd | $\frac{89 \times 103}{203}=45.16$ | $\frac{89 \times 100}{203}=43.84$ |  |
| Flying obs'd | 14 | 16 | 30 |
| Transports exp'd | $\frac{30 \times 103}{203}=15.22$ | $\frac{30 \times 100}{203}=14.78$ |  |
| ot obs'd | 38 | 46 | 84 |
| Flying exp'd | $\frac{84 \times 103}{203}=42.62$ | $\frac{84 \times 100}{203}=41.38$ |  |
| Column Total | 103 | 100 | 203 |
| $\chi^{2}=\frac{(51-45.16)^{2}}{1516}$ | $(38-43.84)$ | $(14-15.22)^{2}$ |  |
| $\begin{gathered} 45.16 \\ (16-14.78) \end{gathered}$ | 3.84 | 15.22 |  |
|  | $)^{2}+\frac{(38-42.62)^{2}}{42.6}$ | $(46-41.38)^{2}$ |  |
| $+\frac{14.78}{}$ | 42.62 | 41.38 |  |

which has $(3-1) \times(2-1)=2$ degrees of freedom.
The approximate $P$-value is greater than 0.25 , not rejecting $\mathrm{H}_{0}$. The difference can be simply due to chance variation. Lecture 25-20

Let's first check Austen's consistency from one work to another. The table below gives the obs'd count and the exp'd count (in paranthesis) in each cell of the table.

|  | Sense and <br> Sensibility | Emma | Sanditon I |
| :---: | :---: | :---: | :---: |
| a | 147 | 186 | 101 |
|  | $(160.0)$ | $(187.8)$ | $(86.2)$ |
| an | 25 | 26 | 11 |
|  | $(22.9)$ | $(26.8)$ | $(12.3)$ |
| this | 32 | 39 | 15 |
|  | $(31.7)$ | $(37.2)$ | $(17.1)$ |
| that | 94 | 105 | 37 |
|  | $(87.0)$ | $(102.1)$ | $(46.9)$ |
| with | 59 | 74 | 28 |
|  | $(59.4)$ | $(69.7)$ | $(32.0)$ |
| without | 18 | 10 | 10 |
|  | $(14.0)$ | $(16.4)$ | $(7.5)$ |

$$
\begin{aligned}
& \chi^{2}=12.27 \text { with } \\
& (6-1) \times(3-1)=10
\end{aligned}
$$

degrees of freedom.
$P$-value is greater than 0.25 .

The relative frequencies with which Austen used these words did not change from work to work.

|  | Upper-tail probability $p$ |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| df | 0.25 | 0.20 | 0.15 | 0.10 | 0.05 | 0.025 | 0.02 | 0.01 | $\ldots$ |
| 10 | 12.55 | 13.44 | 14.53 | 15.99 | 18.31 | 20.48 | 21.16 | 23.21 | $\ldots$ |
| Lecture $25-22$ |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |
